

### Abstract

A communication system includes first and second terminals and an intermediate server that notifies destination information for determining the address of the second terminal. The first terminal  
5 transmits to the intermediate server a request message for requesting the destination information. The intermediate server comprises a storage unit that stores a permitted-terminal table indicative of correspondence between the second terminal and a terminal permitted to be connected with the second terminal; a reception unit for  
10 receiving the request message; and a control part for determining, based on the permitted-terminal table, whether the first terminal that has transmitted the received request message is a terminal permitted, by the second terminal , to be connected with the second terminal, and for notifying the first terminal of the destination  
15 information of the second terminal only if the first terminal is a terminal permitted to be connected with the second terminal.
